\textbf{Background:} There is limited information on the prevalence and multilevel risk factors of long-term opioid use in older nursing home residents despite their high burden of pain and vulnerability to adverse drug events.

\textbf{Objectives:} To estimate the prevalence and correlates of long-term opioid use in United States (US) nursing homes.

\textbf{Methods:} We used comprehensive administrative/claims data (Minimum Data Set 3.0; Medicare Part D) from 2012 to conduct a cross-sectional study of 369,180 long-stay nursing home residents who were Medicare beneficiaries, ≥65 years old, and had no cancer. Resident factors of interest included demographics and physical/cognitive impairment, and facility factors included US census region and structural characteristics (eg, bed size, ownership). Long-term opioid use was defined as ≥90 cumulative days of opioid use during a 120 day observation window - defined using fill dates and days’. Modified Poisson models were used to estimate adjusted prevalence ratios (aPR) and 95\% confidence intervals (CI) between resident/ facility-level characteristics and long-term opioid use.

\textbf{Results:} Nearly one third of long-stay residents used any opioid, with 14.5\% using opioids long-term. Among long-term users, 35.3\% received a long-acting opioid, with 17.1\% receiving high (≥90 mg/day oral morphine equivalents) daily doses. Hydrocodone (49.0\%), tramadol (31.3\%), and fentanyl (24.8\%) were most commonly used. The prevalence of long-term use was higher in women (vs. men; aPR=1.20, 95\% CI: 1.18-1.23) and those with no/mild cognitive impairment (vs. other; aPR=1.18, 95\% CI: 1.16-1.20) or severe physical impairment (aPR=1.25; 95\% CI: 1.22-1.27), and in government-owned nursing homes (vs. for-profit; aPR=1.10, 95\% CI: 1.05-1.16). Long-term use varied by region (10.6\% [Northeast] to 17.7\% [Midwest]) and across facilities (median: 13.3\% interquartile range: 6.7\%-21.3\%).

\textbf{Conclusions:} Long-term opioid use is substantially higher in nursing home residents than what has been previously reported in community-dwelling older adults. Further investigations of opioid safety in this frail population are needed.
