Differential involvement of the microtubule cytoskeleton in insulin receptor substrate 1 (IRS-1) and IRS-2 signaling to AKT determines the response to microtubule disruption in breast carcinoma cells

The insulin receptor substrate (IRS) proteins serve as essential signaling intermediates for the activation of PI3K by both the insulin-like growth factor 1 receptor (IGF-1R) and its close family member, the insulin receptor (IR). Although IRS-1 and IRS-2 share significant homology, they regulate distinct cellular responses downstream of these receptors and play divergent roles in breast cancer. To investigate the mechanism by which signaling through IRS-1 and IRS-2 results in differential outcomes, we assessed the involvement of the microtubule cytoskeleton in IRS-dependent signaling. Treatment with drugs that either stabilize or disrupt microtubules reveal that an intact microtubule cytoskeleton contributes to IRS-2 but not IRS-1-mediated activation of AKT by IGF-1. Proximal IGF-1R signaling events, including IRS tyrosine phosphorylation and recruitment of PI3K, are not inhibited by microtubule disruption, indicating that IRS-2 requires the microtubule cytoskeleton at the level of downstream effector activation. IRS-2 colocalization with tubulin is enhanced upon Taxol-mediated microtubule stabilization, which, together with the signaling data, suggests that the microtubule cytoskeleton may facilitate access of IRS-2 to downstream effectors such as AKT. Of clinical relevance is that our data reveal that expression of IRS-2 sensitizes breast carcinoma cells to apoptosis in response to treatment with microtubule-disrupting drugs, identifying IRS-2 as a potential biomarker for the response of breast cancer patients to Vinca alkaloid drug treatment.

Insulin receptor substrate 1 (IRS-1) and IRS-2 are cytoplasmic adaptors for the insulin receptor (IR) and insulin-like growth factor 1 receptor (IGF-1R), and they play a major role in determining the cellular response to stimulation of these receptors (1). Notably, the IRS proteins are required for the activation of PI3K downstream of the IR and IGF-1R, which activate AKT and mechanistic target of rapamycin (mTOR) to promote proliferation, survival, motility, protein synthesis, and glucose metabolism (2–5). IRS-1 and IRS-2 are expressed ubiquitously in humans, including in the normal and malignant mammary epithelium (1). Despite their considerable sequence homology, IRS-1 and IRS-2 play divergent roles in breast cancer. In vitro studies to assess IGF-1-dependent signaling through the IRS proteins in breast carcinoma cells have revealed that IRS-1 primarily regulates proliferation and survival, whereas IRS-2 regulates motility, invasion, and glycolysis (6–10). In vivo, overexpression of either IRS-1 or IRS-2 in the mouse mammary gland promotes mammary tumorigenesis (11). However, metastasis is diminished in the absence of IRS-2 expression and increased in the absence of IRS-1 expression (9, 12).

Differential localization patterns of IRS-1 and IRS-2 in human breast tumors suggest one explanation for their divergent functions in breast cancer (13). In normal breast tissue, ductal carcinoma in situ, and invasive breast tumors, IRS-1 is primarily localized in the nucleus and also diffusely in the cytoplasm, frequently correlating with nuclear expression of estrogen receptor (14–16). Nuclear expression of IRS-1 also correlates with response to tamoxifen in breast cancer patients (17). IRS-1 has been implicated in the regulation of estrogen response genes through its interaction with the estrogen receptor at estrogen response elements in gene promoters (16). The interaction of IRS-1 with β-catenin and its regulation of genes such as c-Myc and Cyclin D1 likely contribute to its role in stimulating proliferation (18, 19). In contrast to IRS-1, IRS-2 is absent from the nucleus in normal breast and breast tumors and is expressed either in the cytoplasm or at the cell membrane (13). Diffuse cytoplasmic IRS-2 staining is associated with better overall survival of breast cancer patients, whereas membrane localization of IRS-2 in breast tumors is associated with decreased overall survival, particularly in patients with progesterone receptor-negative tumors (13).

The localization pattern of IRS-1 and IRS-2 in human tumors suggests that their trafficking to distinct subcellular compart-
ments contributes to their ability to elicit unique signaling responses. However, the mechanism by which the intracellular localization of IRS-1 and IRS-2 is determined is not known. The microtubule cytoskeleton, which plays an important role in intracellular trafficking, has been implicated in insulin-dependent regulation of glucose uptake, and this role for microtubules occurs distal to IRS phosphorylation (20–22). These observations support a role for microtubules in IRS-mediated downstream signaling, potentially through targeting of these adaptor proteins to unique subcellular compartments. We examined the role of the microtubule cytoskeleton in determining differential signaling and functional outcomes for IRS-1 and IRS-2. The data we obtained in this study reveal that IRS-2 co-localizes with microtubules and that the microtubule cytoskeleton contributes to IRS-2- but not IRS-1-dependent signaling to AKT. The differential involvement of the microtubule cytoskeleton in IRS-1- and IRS-2-mediated AKT signaling influences the apoptotic sensitivity of breast carcinoma cells to microtubule-disrupting drugs.

Results

**IGF-1R signaling is dependent on the microtubule cytoskeleton**

To investigate the role of the microtubule cytoskeleton in IRS-dependent IGF-1R signaling, MDA-MB-231 cells were stimulated with IGF-1 after short-term (30 min to 1 h) treatment with paclitaxel (Taxol) or nocodazole. Taxol, a taxane drug commonly used in cancer treatment, stabilizes microtubules, whereas nocodazole causes depolymerization of the tubulin cytoskeleton (23–25). IGF-1R signaling was measured by assessing the phosphorylation status of AKT, a downstream signaling effector of PI3K, because the IRS proteins are required for the recruitment and activation of PI3K by the IGF-1R (4, 5, 26). Although microtubule stabilization by Taxol treatment did not alter the level of AKT activation (Fig. 1A), disruption of the microtubule cytoskeleton in response to nocodazole treatment significantly reduced phosphorylation of AKT at both threonine 308 and serine 473 (Fig. 1B). IGF-1-dependent AKT activation was also reduced when cells were treated with the *Vinca* alkaloid drug vinblastine, which also disrupts microtubules and is used clinically in chemotherapy regimens (Fig. 1C) (23). Taken together, these results indicate that an intact microtubule cytoskeleton contributes to IRS-dependent activation of AKT by the IGF-1R.

To investigate the mechanism by which nocodazole inhibits AKT activation, phosphorylation of the IGF-1R and IRS proteins and IRS/PI3K association were examined. Treatment with nocodazole did not decrease IRS-1 or IRS-2 tyrosine phosphorylation or association with the p85 regulatory subunit of PI3K in response to IGF-1 stimulation, indicating that activation of

---

**Figure 1. Involvement of the microtubule cytoskeleton in IGF-1-stimulated AKT activation.** MDA-MB-231 cells were treated with DMSO, Taxol (20 μM), nocodazole (1 μM), or vinblastine (20 nm) for 30 min and then stimulated with IGF-1 (20 ng/ml) for 5 min. A—C, aliquots of cell extracts containing equivalent amounts of total protein were immunoblotted with antibodies specific for Ser(P)-473AKT (pAKT S473), Thr(P)-308AKT (pAKT T308), or Thr(P)-202/Tyr-204ERK (pERK). The immunoblots were subsequently stripped and reprobed with total AKT and ERK-specific antibodies. D, aliquots of cell extracts containing equivalent amounts of total protein were immunoprecipitated (IP) with antibodies specific for IRS1, IRS2, or IGF-1R subunit and immunoblotted with antibodies specific for phosphotyrosine (pTyr) and the p85 subunit of PI3K (p85). The Tyr(P) immunoblots were subsequently stripped and reprobed with IRS1, IRS2, or IGF-1R-specific antibodies. Total cell extracts were also immunoblotted with antibodies specific for Ser(P)-473AKT and total AKT (whole-cell lysate [WCL], bottom panels). All immunoblots shown are representative of three independent experiments.
PI3K upstream of AKT was not inhibited by microtubule disruption (Fig. 1D). Of note, expression of the IGF-1R β subunit and its IGF-1-dependent tyrosine phosphorylation were increased following nocodazole treatment (Fig. 1D). We attribute this increase to the accumulation of the activated receptor at the cell surface or in early endosomes, resulting in sustained expression and activation (27).

IRS-2, but not IRS-1, requires the microtubule cytoskeleton to activate AKT

To determine whether there is a selective role for the microtubule cytoskeleton in IRS-1- or IRS-2-mediated signaling, mammary tumor cells derived from PyMT:WT, PyMT:Irs-1−/−, or PyMT:Irs-2−/− tumors were treated with nocodazole and stimulated with IGF-1 (Fig. 2A). WT cells that express both Irs-1 and Irs-2 demonstrated a 40% reduction in Akt activation after treatment with nocodazole. PyMT:Irs-1−/− cells, which signal exclusively through Irs-2, exhibited a further reduction in IGF-1-dependent Akt activation (~50%) following treatment with nocodazole. In contrast, Akt activation was equivalent in PyMT:Irs-2−/− cells, which signal exclusively through Irs-1, in response to IGF-1 stimulation following DMSO or nocodazole treatment.

The role of IRS-2 in the sensitivity of cells to microtubule disruption was explored further using PyMT:Irs-1−/− and PyMT:Irs-2−/− cells that were derived from PyMT:Irs-1−/−β and PyMT:Irs-2−/−β cell lines, respectively, after acute adenosine-Cre infection. PyMT:Irs-2−/−β cells with or without restored IRS-2 expression were stimulated with IGF-1 after treatment with nocodazole and vinblastine. An additional Vinca alkaloid drug, vinorelbine, which is used to treat breast cancer patients (23–28), was also assayed (29). As observed previously (Fig. 2A), disruption of microtubules did not decrease Akt activation in cells lacking Irs-2 expression (Irs2−/−: IRS2) (Fig. 2B). In contrast, the -fold change reduction in Akt activation observed in Irs1−/− cells after nocodazole treatment (50%) was diminished (30%) upon restoration of IRS-1 expression (Irs−/−: IRS1) (Fig. 2C). Taxol treatment did not inhibit Akt activation in mouse mammary tumor cells (Fig. 2C), as was observed for MDA-MB-231 cells (Fig. 1A).

To assess the role of microtubules in IRS-2-mediated signaling in human breast carcinoma cells, IRS2 expression was suppressed by shRNA targeting in MDA-MB-231 cells (Fig. 2D). Total Akt activation in response to IGF-1 stimulation was reduced in shIRS-2 cells compared with shGFP cells (Fig. 2D, second and sixth lanes). Treatment of shGFP cells with either nocodazole or vinblastine significantly reduced AKT activation (Fig. 2D, third and fourth lanes), as was observed for the parental cells (Fig. 1C). In contrast, no significant reduction in AKT phosphorylation occurred in the shIRS2 cells, which signal predominantly through IRS-1, upon treatment with either nocodazole or vinblastine (Fig. 2D, seventh and eighth lanes). The -fold difference in AKT activation observed in shGFP and shIRS2 cells upon microtubule disruption increased with time of stimulation, indicating that microtubules are required to sustain IRS2-dependent signaling (Fig. 2E). Taken together with the mouse cell line data, these results support the hypothesis that an intact microtubule cytoskeleton contributes to IGF-1 signaling through IRS-2 but not IRS-1.

The dependence of IRS2 signaling to Akt on an intact microtubule cytoskeleton indicates a potential interaction of IRS-2 with microtubules. To investigate this possibility, the localization of IRS-1, IRS-2, and tubulin was examined by immunofluorescent staining and confocal imaging. For these experiments, SUM-159 breast carcinoma cells were used because they express both IRS-1 and IRS-2, spread well on coverslips, and retain their spread morphology upon treatment with Taxol and nocodazole, which facilitates detection of co-localization. Both IRS-1 and IRS-2 were expressed in a punctate manner throughout the cytoplasm, with a modest enhancement in the perinuclear region (Fig. 3; left panels). Although no specific pattern of staining was observed for IRS-1, the punctate staining for IRS-2 was more organized, with some apparent alignment along microtubules. To assess further the association of IRS-2 with microtubules, cells were stained after short-term incubation with either Taxol or nocodazole to evaluate their impact on IRS localization. The organized, linear pattern of IRS-2 staining was more apparent upon Taxol stabilization of the microtubules, and a subset of IRS-2 puncta co-localized with tubulin under these conditions (Fig. 3B, center panels). IRS-2 was dispersed throughout the cytoplasm with no tubulin co-localization upon disruption of microtubules by nocodazole (Fig. 3B, right panels). In contrast, IRS-1 staining was not modified in response to Taxol or nocodazole treatment (Fig. 3A).

IRS-2 determines the cellular response to microtubule disruption

Drugs that target the microtubule cytoskeleton are used clinically for the treatment of cancer (23). To investigate how IRS-2 may impact the response of tumors to microtubule-stabilizing or -disrupting drugs, MDA-MB-231 cells were treated for 48 h with either nocodazole or Taxol and then analyzed for viability by propidium iodide staining and flow cytometry analysis. A significant increase in the sub-G1 population occurred in response to both nocodazole and Taxol treatment in shGFP control cells (Fig. 4A), consistent with an induction of cell death. Compared with shGFP cells, cell death was significantly diminished in shIRS-2 cells in response to nocodazole treatment (Fig. 4A). In contrast, when cells were treated with Taxol, which does not inhibit IRS2-mediated AKT signaling (Figs. 1A and 2C), cell death levels were similar for shGFP and shIRS2 cells. To further investigate the clinical relevance of the IRS2-dependent sensitivity of breast carcinoma cells to microtubule disruption, MDA-MB-231 cells were treated with vinblastine or vinorelbine, both of which are used in the treatment of solid tumors, including breast cancer (23). As was observed for nocodazole treatment, cell death was significantly diminished in shIRS2 cells treated with either vinblastine or vinorelbine compared with shGFP-treated cells (Fig. 4B).

A similar resistance to cell death upon treatment with nocodazole was observed for PyMT:Irs2−/− cells compared with parental cells (PyMT:Irs2−/−β) or Irs2−/− cells in which WT Irs-2 expression was restored (Irs2−/−β:IRS2) (Fig. 5A). In contrast, restoration of IRS1 expression to PyMT:Irs1−/− cells
reduced cell death in response to nocodazole treatment (Fig. 5B). Similar to MDA-MB-231 cells, cell death in response to Taxol treatment was not dependent upon Irs expression in PyMT mammary tumor cells (Fig. 5A and B).

As has been reported previously, cells undergo a G2/M arrest in response to microtubule disruption or stabilization (30). The cell cycle profiles of cells treated with nocodazole or Taxol were analyzed to determine whether IRS2 expression influences the cell cycle response to microtubule-targeting drugs. MDA-MB-231:shGFP cells exhibited an increase in G2/M arrest when treated with nocodazole (Fig. 4C). In contrast, a significantly higher percentage of MDA-MB-231:shIRS2 cells remained in G2/M phase (Fig. 4D).

Figure 2. Selective requirement of the microtubule cytoskeleton for IRS-2-mediated signaling. A, PyMT:WT, PyMT:irs-1−/− and PyMT:irs-2−/− cells were treated with DMSO or 20 μM nocodazole (Noc) for 1 h and then stimulated with IGF-1 (10 ng/ml) for 5 min. B, PyMT:irs-1−/− cells transfected with empty vector (irs2−/−) or IRS2 (irs2−/−:IRS2) were treated with DMSO, 1 μM nocodazole, 20 nM vinblastine (Vin), or 20 nM vinorelbine (Vino) for 1 h and then stimulated with IGF-1 (10 ng/ml) for 15 min. C, PyMT:irs-1−/− cells transfected with empty vector (irs1−/−) or IRS1 (irs1−/−:IRS1) were treated with DMSO, 1 μM nocodazole, or 10 μM Taxol for 1 h and then stimulated with IGF-1 (10 ng/ml) for 5 min. D, MDA-MB-231 cells expressing either an shRNA targeting GFP (shGFP) or IRS2 were treated with DMSO, 1 μM nocodazole, or 20 nM vinorelbine for 30 min and then stimulated with IGF-1 (10 ng/ml) for 30 min. E, MDA-MB-231 cells expressing either an shRNA targeting GFP or IRS2 were treated with DMSO or 1 μM nocodazole for 30 min and then stimulated with IGF-1 (10 ng/ml) for the time periods indicated. The data in the graph represent the -fold change in phospho-AKT between DMSO- and nocodazole-treated cells for each cell type. Aliquots of cell extracts containing equivalent amounts of total protein were immunoblotted with antibodies specific for IRS1, IRS2, Ser(P)-473AKT, total AKT, tubulin, or GAPDH. The data shown in the graphs for each immunoblot represent the mean ± S.E. of three independent experiments. *, p ≤ 0.05 relative to shGFP; **, p ≤ 0.01 relative to shGFP.

IRS2 signaling to AKT involves microtubules
In this study, we demonstrate a differential involvement of the microtubule cytoskeleton in IRS-dependent activation of AKT. AKT activation in response to IGF-1 stimulation is maintained when the microtubule cytoskeleton is disrupted in cells that signal only through IRS-1. In contrast, microtubule disruption significantly diminishes AKT activation when the IGF-1R signals through IRS-2. Proximal IGF-1R signaling events, including receptor tyrosine phosphorylation, IRS tyrosine phosphorylation, and recruitment of PI3K, are not inhibited by microtubule disruption, indicating that IRS-2 requires the microtubule cytoskeleton at the level of downstream effector activation. The co-localization of IRS-2, but not IRS-1, with tubulin is enhanced upon Taxol-mediated microtubule stabilization, which, in concert with the signaling data, suggests an interaction of IRS-2 with the microtubule cytoskeleton that may facilitate its access to effectors such as AKT. Functionally, IRS-2 sensitizes breast carcinoma cells to apoptotic cell death in response to treatment with microtubule-disrupting drugs through a mechanism involving the inhibition of AKT signaling and regulation of the BH3-only apoptotic activator BIM. Our

Figure 3. Intracellular localization of IRS proteins and co-localization with microtubules. A and B, SUM159 cells were treated with either DMSO, 20 µM Taxol, or 1 µM nocodazole (Noc) for 1–2 h before fixation. Fixed cells were co-stained for IRS-1 or IRS-2 (green) and tubulin (red). Individual images for IRS-1/IRS-2 and merged IRS/tubulin images are shown (magnification ×63).

Discussion

Given that AKT signaling is selectively resistant to microtubule disruption in cells deficient for IRS2 expression, we hypothesized that the resistance of these cells to nocodazole-mediated cell death was the result of sustained AKT signaling in these cells. To test this hypothesis, cells were treated with nocodazole for 48 h in the presence or absence of an AKT-specific inhibitor, MK2206. Treatment of MDA-MB-231 shGFP and shIRS2 cells with MK2206 alone did not alter the percentage of sub-G₁ cells (Fig. 6A) or cell cycle profile (Fig. 6, B and C), as has been reported previously for parental MDA-MB-231 cells at the concentration of inhibitor used in these assays (28). This concentration of MK2206 was, however, sufficient to inhibit AKT activation (Fig. 6D). Combined treatment of the MDA-MB-231:shGFP cells with MK2206 and nocodazole did not increase cell death (Fig. 6A) or alter cell cycle progression (Fig. 6B). In contrast, addition of MK2206 to the nocodazole-treated MDA-MB-231:shIRS2 cells increased the percentage of sub-G₁ cells to that observed for shGFP cells treated with nocodazole alone (Fig. 6A). Combined treatment with MK2206 and nocodazole also promoted G₂/M arrest in these cells, restoring the cell cycle profile to that of the nocodazole-treated, IRS2-expressing cells (Fig. 6C).

To investigate the mechanism of cell death in response to microtubule disruption, cell extracts from MDA-MB-231 cells treated with nocodazole for 48 h in the presence or absence of MK2206 were immunoblotted for cleaved caspase 3. Caspase 3 cleavage increased significantly upon treatment of shGFP cells with nocodazole, confirming that these cells undergo apoptotic cell death (Fig. 7A) (31). Cleaved caspase 3 levels were significantly lower in shIRS2 nocodazole-treated cells. However, combined treatment of shIRS2 cells with both nocodazole and MK2206 increased caspase 3 cleavage, supporting a role for AKT signaling in the enhanced viability of these cells. Analysis of upstream apoptotic effectors identified the BCL2 homology 3 (BH3)-only protein BIM as a potential regulator of caspase 3 activation in response to microtubule disruption (31). Specifically, the BIM-EL and BIM-L isoforms of BIM were expressed at elevated levels in shGFP cells compared with shIRS2 cells, and expression increased upon co-treatment with MK2206 in shIRS2 cells (Fig. 7B).
data identify IRS-2 as a potential biomarker for the response of breast cancer patients to Vinca alkaloid drug treatment.

The IRS proteins function as signaling intermediates for both the IGF-1R and IR. Previous studies have investigated the importance of the microtubule cytoskeleton in signaling through the IR in insulin-responsive cell types such as adipocytes and muscle (20, 21). Similar to our findings with IGF-1R signaling, proximal IR signaling events are not impacted by microtubule disruption, whereas distal events such as GLUT4 translocation to the plasma membrane are inhibited (20). The impact of microtubule disruption on AKT activation in response to insulin stimulation is cell type-dependent. Insulin-induced AKT activation was modestly reduced in 3T3-L1 adipocytes, maintained in CHO cells that express IR and IRS-1 (CHO.IR.IRS-1), and inhibited in skeletal muscle cells upon treatment with microtubule-disrupting drugs (21, 32). Importantly, the involvement of either IRS-1 or IRS-2 was not investigated in these different cell models. The differential expression and activation of IRS-1 and IRS-2 in each cell type may explain the differential responses of these cells to microtubule disruption.

Our demonstration that IRS-1 and IRS-2 differ in their dependence upon an intact microtubule cytoskeleton for their downstream signaling adds to the mechanistic understanding of how signaling by these homologous proteins regulates distinct functional outcomes. IRS-1 and IRS-2 are both capable of recruiting PI3K and activating AKT, but the functional response to this activation is quite different for each adaptor protein (1). Stimulation of cells with insulin or IGF-1 promotes proliferation when IRS-1 is the dominant signaling adaptor (8, 33). Although a direct role for AKT in this response has not been demonstrated, it is dependent upon activation of PI3K (33). In contrast, stimulation of breast carcinoma cells that express IRS-2 as the dominant signaling adaptor respond by increasing migration/invasion and glycolytic metabolism (7–10). IRS-2-dependent activation of PI3K is also required for these cellular responses (5). With regard to metabolism, the ability of IRS-2 to selectively regulate distinct downstream AKT effectors contributes to this differential outcome. IRS-2-dependent activation of AKT results in the phosphorylation and inactivation of GSK3, and this inactivation is required for IRS-2-mediated regulation of glucose uptake (5). In this study, expression of the apoptotic activator BIM increased in response to disruption of IRS-2-dependent AKT activation, a mechanism that may involve the selective regulation of another AKT effector pathway. Specifically, BIM expression is positively regulated by FOXO transcription factors, which are inactivated by AKT phosphorylation (34–36). IRS-2 has been shown previously to mediate insulin regulation of Foxo1 activity and Bim expression in neonatal mouse hepatocytes (37).

Our data support the hypothesis that the ability of IRS-2 to interact with and potentially traffic along microtubules may determine its access to distinct subsets of effectors to elicit unique functional responses. Of note, a selective role for IRS-1- and IRS-2-dependent signaling in skeletal muscle has been reported that involves differential AKT isoform activation. Insulin-stimulated myoblast differentiation and glucose metabolism are regulated by IRS-1/AKT2 signaling, whereas signaling through IRS-2/AKT1 controls lipid metabolism (38). The possibility that AKT isoforms are selectively sensitive to microtubule disruption could contribute to the differential sensitivity of IRS-1 and IRS-2 to microtubule loss.

The results of this study are consistent with the work of other groups that suggests a central role for AKT in the tumor cell response to microtubule-disrupting drugs (39–41). Specifically, AKT promotes the phosphorylation of microtubule-binding proteins that stabilize microtubules and, in doing so, increases the resistance of tumor cells to drugs that function by

**Figure 4. The Role of IRS-2 in the cellular response to microtubule disruption.** A—D, MDA-MB-231 cells were treated with DMSO or the indicated drugs for 48 h. The cells were stained with propidium iodide and analyzed by flow cytometry. Shown are the percentages of cells in the sub-G0 peak (A and B) or cell cycle stages (C and D). The data shown represent the mean of representative experiments performed three times (± S.E.) (nocodazole, vinblastine, and vinorelbine) or twice (± S.D.) (Taxol) independently. *, p ≤ 0.05 relative to shGFP; **, p ≤ 0.01 relative to shGFP.
disrupting the microtubule cytoskeleton. Our data now reveal that the mechanism by which tumor cells regulate AKT activity will also influence the response to these drugs. Our results have implications for the use of microtubule-disrupting drugs, such as vinblastine and vinorelbine, for the treatment of breast cancer. The differential responses of IRS-1- and IRS-2-dependent signaling to these chemotherapeutic drugs raise the possibility that IRS-2 may influence how breast tumors respond to Vinca alkaloid drug treatment. We reported previously that expression of IRS-2 at the cell membrane is associated with a statistically significant decrease in overall survival in breast cancer patients (13). We hypothesize that IRS-2 at the cell membrane is indicative of active signaling, and patients who have tumors with this staining pattern may be more sensitive to microtubule-disrupting drugs than patients without active IRS-2 signaling. Moreover, breast tumors with low IRS2 expression/function could be responsive to combination therapies that pair an AKT inhibitor with a Vinca alkaloid drug. Therefore, IRS-2 could be used as a biomarker to identify patients for targeted treatment with these drugs.

**Experimental procedures**

**Cell lines, shRNA, and transfection**

The MDA-MB-231 cell line was obtained from the ATCC Cell Biology Collection. SUM-159 cells were a kind gift from Dr. Art Mercurio (UMass Medical School, Worcester, MA). WT, Irs-1−/−, and Irs-2−/− mammary tumor cell lines were established from MMTV-PyV-MT-derived tumors as described previously (9). Irs−1/fl/fl and Irs−2/fl/fl mammary tumor cells were isolated from female FVB MMTV-PyMT::Irs−1/fl/fl and MMTV-PyMT::Irs−2/fl/fl mice, respectively, and Irs−1/fl/fl cells

---

**Figure 5. The differential impact of Irs1 and Irs2 on the cellular response to microtubule disruption.** A—G, PyMT cells were treated with DMSO or the indicated drugs for 48 h. The cells were stained with propidium iodide and analyzed by flow cytometry. Shown are the percentages of cells in the sub-G1 peak (A and B) or cell cycle stages (C–G). The data shown represent the mean ± S.E. of represesative experiments performed three times or twice (Taxol/Irs2 cells) independently. 2fl/fl, PyMT:irs2/fl/fl cells; 2−/−, PyMT:irs2−/− cells; 2−/−:IRS2, PyMT:irs2−/−:IRS2 cells; 1−/−, PyMT:irs1−/− cells; 1−/−:IRS1, PyMT:irs1−/−:IRS1 cells. *, p ≤ 0.05 relative to Irs−1/fl/fl; **, p ≤ 0.001 relative to Irs−1/fl/fl.
were generated by infection with adenoviral Cre-recombinase as described previously (5). Lentiviral vectors containing shRNAs targeting GFP and human IRS-2 were obtained from Open Biosystems (Huntsville, AL). MDA-MB-231 cells were infected with the virus, and stably expressing cells were selected by the addition of 2 μg/ml puromycin. IRS expression was restored in Irs−/− mammary tumor cells by transfection with HA-tagged human IRS-1 or IRS-2 (kindly provided by Adrian Lee, University of Pittsburgh, Pittsburgh, PA) and selection in G418 (0.5 mg/ml) (11).

Immunoblotting and immunoprecipitation

Cells were either serum-starved overnight (MDA-MB-231) or for 4 h (PyMT cells) in serum-free medium. Drugs were added to the medium prior to stimulation with IGF-1. MDA-MB-231 cells were treated with nocodazole or vinblastine for 30 min and Taxol for 2 h. The mouse tumor cell lines were treated with nocodazole, vinblastine, or vinorelbine for 1 h. The concentrations (see figure legends) and time periods of incubation were determined to stabilize or disrupt the microtubule cytoskeleton, as assessed by immunofluorescence staining for tubulin. For microtubule-altering drugs, paclitaxel (T7402) was obtained from Sigma-Aldrich (St. Louis, MO), and nocodazole (S2775), vinblastine (S1248), and vinorelbine (S4269) were obtained from Selleckchem (Houston, TX). MK2206 (S1078) was obtained from Selleckchem. Cells were stimulated for 5–30 min with human recombinant IGF-1 (R&D Systems, Minneapolis, MN) prior to extraction.

For total cell extract immunoblots, cells were solubilized at 4 °C in radioimmune precipitation assay lysis buffer (25 mM Tris (pH 8.0), 0.1% sodium dodecyl sulfate, 1% sodium deoxycholate, 1% Nonidet P-40, 150 mM sodium chloride, 10 mM sodium fluoride, and 1 mM sodium orthovanadate) containing protease inhibitors (Roche). Cell extracts containing equivalent amounts of protein were resolved by SDS-PAGE and transferred to nitrocellulose membranes. The membranes were blocked for 1 h with a 50 mM Tris buffer (pH 7.5) containing 0.15 M NaCl, 0.05% Tween 20, and 5% (w/v) dry milk or 5% BSA, incubated overnight at 4 °C in the same buffer containing primary antibodies, and then incubated for 1 h in 5% blocking buffer with milk containing peroxidase-conjugated secondary antibodies. Proteins were detected by enhanced chemilumines-
IRS2 signaling to AKT involves microtubules

Immunofluorescence microscopy

Subconfluent, adherent cells plated on glass coverslips were treated with nocodazole (1 μM) for 1 h or Taxol (20 μM) for 2 h. Cells were washed three times with Dulbecco’s PBS and fixed in 3.8% paraformaldehyde in Dulbecco’s PBS with 0.5% Tween (PBST) for 1 h. Permeabilized cells were blocked for 1 h using 3% BSA in PBST. Primary antibodies diluted in blocking buffer were added to cells and incubated at room temperature for 1 h. Secondary antibodies were diluted in the same buffer, and cells were incubated at room temperature for an additional 30 min. Cells were washed three times with PBST after each antibody incubation. Coverslips were then mounted on glass slides using Prolong Gold containing DAPI (Cell Signaling Technology), and the slides were viewed by confocal microscopy (Zeiss LSM700, ×63 oil immersion objective). All images were adjusted equally for brightness/contrast using ImageJ software. Antibodies used for immunofluorescence included IRS-1 (H165, Santa Cruz Biotechnology), IRS-2 (NB110-57138, Novus, Littleton, CO), α-tubulin (T5168, Sigma-Aldrich), Alexa Fluor 488 donkey anti-rabbit IgG (A-21206, Thermo Fisher Scientific, Waltham, MA), and Alexa Fluor 568 donkey anti-mouse IgG (A10037, Thermo Fisher Scientific). The specificity of the IRS-1 and IRS-2 antibody staining was validated by staining PyMT:Ir1−/−, Ir2−/− double-null cells that were transfected with either empty vector, IRS-1, or IRS-2 (supplemental Fig. 1).

Cell cycle analysis

MDA-MB-231 cells were treated with nocodazole (1 μM), vinblastine (20 nM), vinorelbine (20 nM), or MK2206 (250 nM) for 48 h. The mouse PyMT mammary tumor cell lines were treated with nocodazole (1 μM) or Taxol (1 or 10 μM) for 48 h. Adherent cells were collected by trypsinization after treatment and combined with non-adherent cells from the culture medium for cell cycle analysis. After centrifugation, the cell pellet was washed once in cold PBS, and the cells were then fixed in 70% methanol and stored overnight at −20 °C. The fixed cells were washed once in PBS and then resuspended in PBS containing 0.1% Triton X-100, 0.1 mM EDTA, 0.05 mg/ml RNase A (50 units/ml), and 50 μg/ml propidium iodide. The cells were analyzed by flow cytometry using a BD Biosciences FACS Calibur after 1-h incubation at room temperature.
IRS2 signaling to AKT involves microtubules

Supplemental Figure 1: Validation of IRS1 and IRS2 antibodies. PyMT:Irs1-/-,Irs2-/- double null cells were transfected with either empty vector (pcDNA), HA-IRS1 or HA-IRS2. Fixed cells were stained with the indicated IRS1 or IRS2-specific antibodies. Magnification 63x; Bar = 20µM
Differential involvement of the microtubule cytoskeleton in insulin receptor substrate 1 (IRS-1) and IRS-2 signaling to AKT determines the response to microtubule disruption in breast carcinoma cells
